ABSTRACT

Hemothysys is symptomatic of potentially serious and life-threatening chest disease and requires urgent evaluation and treatment. The aim of this study was to evaluate the hemostatic efficacy of endobronchial application of Ankaferd Blood Stopper® (ABS) solution in patients with hemothysys.

This retrospective study included 20 patients with hemothysys in whom endobronchial ABS was applied in 25 bronchoscopic procedures.

Endobronchial application of ABS was successful in 23 of the 25 bronchoscopic procedures. ABS application was repeated due to recurrent bleeding in 4 patients.

This is the first case series demonstrating the endobronchial application of ABS, a novel hemostatic agent, effective in the management of bleeding, especially in local endobronchial malignant lesions. Bronchoscopic ABS application may be an alternative supportive therapeutic method in cases of uncontrolled hemothysys.

Tratamiento efectivo de la hemoptisis mediante aplicación endobronquial del hemostático Ankaferd

RESUMEN

La hemoptisis es una manifestación sintomática de una enfermedad torácica que puede ser grave y poner en peligro la vida, y requiere una evaluación y tratamiento urgentes. El objetivo del presente estudio fue evaluar la eficacia hemostática de la aplicación endobronquial de la solución Ankaferd Blood Stopper® (ABS) en pacientes con hemothysys.

Este estudio retrospectivo se realizó en 20 pacientes con hemothysys en los que se aplicó ABS endobronquial mediante 25 broncoscias.

La aplicación endobronquial de ABS tuvo éxito en 23 de las 25 broncoscias. Se repitió la aplicación de ABS a causa de una recidiva hemorrágica en 4 pacientes.

Esta es la primera serie de casos que describe el uso de la aplicación endobronquial de ABS, un nuevo agente hemostático que constituye un método eficaz para el tratamiento de la hemorragia, sobre todo en lesiones malignas endobronquiales locales. Pensamos que la aplicación broncoscópica de ABS puede ser un método terapéutico alternativo y de apoyo en casos de hemoptisis no controlada.

Introduction

Ankaferd hemostat (Ankaferd Blood Stopper® [ABS]) is an extract of popular medicinal plants that has been used as a hemo-

static agent in traditional Turkish medicine. It consists of a standard mixture of plants, all of which have antithrombin, antiplatelet, antioxidant, antiatherosclerotic and antitumor activity. The basic mechanism of action of ABS is the formation of an encapsulated protein network that provides a focus for vital erythroid aggregation. The paradoxical antithrombotic action of an antihemorrhagic product can be explained by its effects on gamma fibrinogen seen in functional proteome analysis. ABS was recently registered for the treatment of clinical bleeds when conventional control methods are ineffective. The aim of this study was to evaluate retrospectively

* ABS applied directly via the bronchoscopic probe.
+ Catheter: ABS applied via a catheter.
* ABS applied in 3 different bronchoscopic tumor debulking sessions.
* Bronchoscopy repeated after radiotherapy session due to recurrent hemoptysis.
* No endobronchial lesion observed in second intervention.
* ABS application repeated 1 day after the first application when bleeding recurred.
* The second bleeding episode was also massive in these patients.
* ABS application was repeated 2 days after the first application due to recurrent bleeding.
the efficacy of the endobronchial application of ABS hemostat in the treatment of hemoptysis.

Patients and methods

ABS was used in 20 patients (18 men and 2 women) who underwent 25 local bronchoscopies with flexible fiberoptic bronchoscope (Olympus® BFXT20, BF-1T160 and Pentax® 18P). Informed consent was obtained from all patients before performing the bronchoscopy. The main indication for the use of ABS was the control of bleeding originating in the bronchial tree that persisted despite lavage of the affected segment with saline cooled in ice and/or adrenaline instillation in the bleed site. In 7 cases, bleeding began after an endobronchial or transbronchial biopsy, and in the other 13 there was diffuse or local endobronchial bleeding. If the bleeding lesion was visible, ABS was applied directly onto the bleed site via the bronchoscopic probe. If there was diffuse bleeding in a lung segment, ABS was applied from the main carina with a bronchoalveolar lavage catheter. The 2 ml dose was repeated if response was insufficient. Depending on the amount of daily bleeding (hemoptysis severity), patients were assigned to 4 groups as follows, mild: only hematic streaks in sputum; moderate: 30-100 cm³; severe: 100-600 cm³; massive: > 600 cm³. Successful control of bleeding after ABS application was defined as cessation of bleeding during the bronchoscopic intervention and no hemorrhagic relapse over a 24-hour period.

Results

The mean age of patients was 58 years (range, 25-81 years). Hemoptysis was the presenting symptom in 13 patients and in 7 it was bleeding after bronchoscopic biopsy. Bleeding could be controlled with ABS a few seconds after instillation in the hemorrhagic focus in 23 interventions, but it was ineffective in 2 cases. ABS was reapplied due to relapsed bleeding in 4 patients in whom hemoptysis recurred within 24 hours after the first intervention. Clinical characteristics of patients are listed in Table 1.

Eight patients had hemorrhagic endobronchial lesions due to lung cancer, with tumor infiltration of the mucosa in one. Bleeding began after transbronchial biopsy in one patient and after a tracheal aspiration procedure in another.

In 9 of the patients, hemoptysis was due to non-malignant causes (Table 1). Six patients had massive bleeding (5 in the non-malignant group and one in the malignant group). Vasculitis was the most common cause of massive bleeds.

Discussion

The aim of this study is to describe an alternative therapeutic option in emergency settings using the endobronchial application of ABS. Endobronchial application of a dose of 2-4 ml ABS was found to be effective in most situations. Due to the fast action of ABS, hemorrhage can be controlled in a few seconds after application. This drug was particularly effective in local hemorrhagic lesions. Only one case of endobronchial application of ABS for the control of a malignant endobronchial lesion has been described. However, the topical administration of ABS has been successfully tested in many other bleeding situations, such as gastrointestinal hemorrhage, epistaxis, hemorrhages in hemophilic, dental bleeds and posttonsillectomy bleeding. Lung cancer was the underlying cause of the majority of cases in this series (11 patients) and in 7 cases, bleeding began after biopsy. The endobronchial application of ABS stopped bleeding in all cases, thus preventing unnecessary diagnostic and curative delays in patient management. In this study, there were 5 cases of massive hemoptysis in patients without cancer. In all these patients, ABS was effective in the treatment of pulmonary bleeding. Moreover, immunosuppressive treatment in vasculitis and supportive treatment in hemoptysis due to welding fumes improved clinical and radiological results.

To conclude, this is the first case series describing the use of endobronchial application of ABS, a new hemostatic treatment representing an effective method for the treatment of bleeding, particularly in local endobronchial malignant lesions. Consequently, bronchoscopic application of ABS may be an alternative supportive treatment in cases of uncontrollable hemoptysis. More controlled, prospective clinical studies will be necessary to fully identify the safety, dosage regimen and efficacy of the topical use of ABS in patients with hemoptysis.
